Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

EP 0 264 166 B1

Description

This invention relates to transgenic animals.

It is possible to insert foreign genes into vertebrate embryos, and for these genes to be incorporated into the genome of the resulting animal. Insertion of the foreign genes has been carried out mechanically (by microinjection), and with the aid of retrovirus vectors (for example, as is described in Huszar et al. (1985) P.N.A.S. U.S.A 82, 8587). The animals resulting from this process are termed "transgenic." The foreign genes can be sexually transmitted through subsequent generations and are frequently expressed in the animal. In some instances the proteins encoded by the foreign genes are expressed in specific tissues. For example, the metallothionein promoter has been used to direct the expression of the rat growth hormone gene in the liver tissue of transgenic mice (Palmiter et al., 1982 Nature 300: 611). Another example is the elastase promoter, which has been shown to direct the expression of foreign genes in the pancreas (Ornitz et al., 1985 Nature 313:600). Developmental control of gene expression has also been achieved in transgenic animals, i.e., the foreign gene is transcribed only during a certain time period, and only in a particular tissue. For example, Magram et al. (1985, Nature 315:338) demonstrated developmental control of genes under the direction of a globin promoter, and Krumlauf et al. (1985, Mol. Cell. Biol. 5:1639) demonstrated similar results using the alpha-feto protein minigene.

In a first aspect thereof, the invention features a DNA sequence containing a gene encoding a protein, the gene being under the transcriptional control of a mammalian casein or milk serum protein promoter which does not naturally control the transcription of the gene, the DNA sequence further including DNA enabling secretion of the protein; e.g., a secretion signal-encoding sequence interposed between the gene and promoter. The promoter can be that of a milk serum protein or a casein protein, although milk serum proteins are preferred, as will be discussed in more detail below. (As used herein, "gene" refers to both genomic DNA sequences and cDNA sequences.)

The invention permits the production of any desired protein in an easily maintained stable, portable culture system, i.e., a living domesticated mammal, which is capable not only of producing the desired protein, but preferably of passing on the ability to do so to its female offspring as well. Secretion of the protein into the host mammal's milk facilitates purification and obviates removal of blood products and culture media additives, some of which can be toxic or carcinogenic. More importantly, protein yields will be high and production will be more cost effective and efficient.

The invention provides, in a third and further alternative aspect thereof, a method for producing a protein comprising the steps of:

- (a) inserting into a non-human mammalian embryo a DNA sequence comprising a gene encoding said protein, said gene being under the transcriptional control of casein or milk serum protein promoter which does not naturally control the transcription of said gene, said DNA sequence comprising DNA enabling secretion of said protein,
- (b) allowing said embryo to develop into an adult mammal,
- (c) inducing lactation in said mammal, or in a female descendant of said mammal in which said gene, promoter, and signal sequence are present in the mammary tissue genome,
- (d) collecting milk of said lactating mammal, and
- (e) isolating said protein from said collected milk.

The invention is hereinafter more particularly described by way of example only with reference to the accompanying drawings, in which:-

Fig. 1 is a diagrammatic representation of the construction of an embodiment of intermediate vector in accordance with the present invention, namely pt-PA VPI-LP(K);

Fig. 2 is a diagrammatic representation of the construction of another embodiment of intermediate vector in accordance with the invention, namely pWAP (H₃);

Fig. 3 is a diagrammatic representation of the construction of another vector in accordance with the invention, namely pWAP-t-PA(S);

Fig. 4 is a diagrammatic representation of the construction of another intermediate vector in accordance with the invention, namely pHbsSVA; and

Fig. 5 is a diagrammatic representation of the construction of another vector according to the invention, namely pWAP-Hbs (S).

DNA Sequence Elements

Promoter

The milk protein promoter can be derived from any mammalian species, and can be any promoter naturally asso-

ciated with any protein which is normally secreted into mammalian milk. Generally, milk proteins are classified as the caseins, which are defined herein as the milk proteins which are present in milk in the form of micelles, and which are removed from skim milk by clotting with rennet; and the milk serum proteins, which are defined herein as the non-casein milk proteins. Whey proteins constitute the predominant fraction of the milk serum proteins, and in rodents include the protein known as whey acid protein. Whey acid protein ("WAP") is named based on its acidic isoelectric point (Piletz (1981) *J. Biol. Chem.* **256**: 11509). Another example of a milk serum protein described in the literature is α -lactalbumin (described, along with mouse WAP, in Hennighausen and Sippel (1982) *Eur. J. Biochem.* **125**, 131). Milk proteins are discussed in detail in Walstra and Jenness *Dairy Chemistry and Physics* (John Wiley & Sons 1984).

Generally, milk serum protein promoters are preferable to casein promoters in the practice of the present invention because caseins generally are produced in female mammals during pregnancy as well as after birth, while WAP is expressed primarily during post-partum lactation. This difference is of potential importance for two reasons. First, pre-birth production of the desired protein under the transcriptional control of a casein promoter could be wasteful, since the protein cannot be isolated from milk until it is secreted into the milk post-partum. Second, where the desired protein is toxic in large amounts (human tissue plasminogen activator (t-PA) is an example), a build-up of the protein in the tissues prior to lactation could be deleterious to the health of the host mammal. An additional advantage of some whey promoters such as the WAP promoter is that they are strong promoters, as evidenced by the large amounts of some whey proteins present in milk. Casein promoters also have this advantage.

Milk protein genes from which promoters, in addition to the WAP promoters, can be isolated, can be obtained in the same manner in which the WAP genes were isolated, as described in Hennighausen and Sippel, *id.*, and Campbell et al. (1984) *Nucleic Acids Research* **12**, 8685. The method generally involves isolating the mRNA from a lactating mammary gland, constructing a cDNA library from the mRNA, screening the library for the particular milk protein cDNA being sought, cloning that cDNA into vectors, and using the appropriate cDNA as a probe to isolate the genomic clone from a genomic library. A sequence upstream from the transcription start site in the genomic clone constitutes a putative "promoter", a genomic sequence preceeding the gene of interest and presumed to be involved in its regulation. The promoter may be isolated by carrying out restriction endonuclease digestions and subcloning steps. Promoters need not be of any particular length nor to have directly shown any properties of regulation. The mouse WAP promoter was isolated as a 2.6 kb *EcoRI* - *KpnI* fragment immediately 5' to the WAP signal sequence.

Desired Protein

Any desired protein can be produced according to the invention. Preferred proteins are proteins useful in the treatment, prevention, and/or diagnosis of human disease; examples are t-PA and hepatitis B surface antigen. The invention is particularly useful for proteins which must be produced on a large scale to be economical, e.g., industrial enzymes and animal proteins.

Signal Sequence

It is necessary, for secretion of the desired protein into the milk of the host mammal, that the DNA sequence containing the gene for the desired protein include DNA which, when translated, causes the protein to be secreted out of the mammary tissue into the milk. Without such a sequence, the desired protein would remain in the mammary tissue, from which purification would be difficult, and would require sacrifice of the host animal. This DNA can encode a hydrophobic secretion signal which is cleaved during secretion. The signal sequence can be that which is naturally associated with the desired protein, if the protein is normally secreted (e.g., t-PA). Alternatively, the signal encoding sequence can be that of the milk protein providing the promoter, i.e., when the milk protein gene is digested and the promoter isolated, a DNA fragment is selected which includes both the promoter and the signal encoding sequence directly downstream from the promoter. Another alternative is to employ a signal encoding sequence derived from another secreted protein, which is neither the milk protein normally expressed from the promoter nor the desired protein.

Termination Site

Preferably there is located within or downstream from the 3' end of the desired gene a termination site. This site may be provided by sequences in the gene itself, or may need to be added. If the sequence is to be added, a preferred sequence is provided by the polyadenylation sequence of the virus SV40, as will be described in greater detail below.

Methods

Genetic Manipulations

Generally, all DNA manipulations used in the genetic constructions described herein may be carried out using conventional techniques, as described, e.g., in Maniatis et al. Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Laboratory, 1982).

Introduction of DNA into Embryos

Once the genetic constructions have been produced in vectors, e.g., plasmids, the promoter-signal sequence-desired protein-termination sequence DNA fragment is excised and then introduced into the desired mammalian embryo using, e.g., retroviruses or standard microinjection methods such as are described in Kraemer et al. (1985), Constantini and Jaenisch, eds., Genetic Manipulation of the Early Mammalian Embryo, Cold Spring Harbor Laboratory (bovine embryo microinjection); Hammer et al. (1985) Nature **315**, 680 (rabbit, sheep, and porcine embryo microinjection); and Gordon and Ruddle (1984) Methods in Embryology **101**, 411 (mouse embryo microinjection). Microinjection is preferably carried out on an embryo at the one-cell stage, to maximize both the chances that the injected DNA will be incorporated into all cells of the animal, including mammary tissue, and that the DNA will also be incorporated into the germ cells, so that the animal's offspring will be transgenic as well. Microinjection is a standard technique which involves, briefly, isolating fertilized ova, visualizing the pronucleus, and then injecting the DNA into the pronucleus by holding the ova with a blunt holding pipette of a diameter on the order of 50 μ m, and using a sharply pointed pipette of a diameter on the order of 1.5 μ m to inject buffer-containing DNA into the pronucleus. Following microinjection, the transgenic female animals are allowed to become sexually mature, mated, and milk collected post-partum.

Preferred host mammals are those which are already bred for large volume milk production, e.g., cows, sheep, goats, and pigs.

t-PA Production

There will now be described the construction of plasmid DNA in which the gene encoding human uterine t-PA, including the signal encoding sequence, is under the transcriptional control of the mouse WAP promoter, and has at its 3' end the SV40 polyadenylation site. This DNA was made from two intermediate plasmids, one carrying the mouse WAP promoter and one carrying the t-PA signal and structural sequences, as well as the SV40 polyadenylation site.

The WAP promoter containing plasmid pWAP-CAT (Fig. 2, obtained from Lothar Hennighausen, National Institutes of Health) was derived from a plasmid made according to the methods described in Hennighausen and Sippel (1982) Eur. J. Biochem. **125**, 131; and Campbell et al. (1984) Nucleic Acids Research **12**, 8685. In addition to containing the mouse WAP promoter, pWAP-CAT contains a gene which, for present purposes, is irrelevant: the CAT (chloramphenicol acetyltransferase) gene, which does not form a part of the final DNA sequence which is microinjected.

Still referring to Fig. 2, pWAP-CAT was modified to convert the EcoRI site to a HindIII site using Klenow and HindIII linkers.

The t-PA-containing plasmid pt-PA-VPI-LP(K) (Fig. 1) was derived from pt-PAVPI-LP, containing the t-PA gene (including the t-PA signal encoding sequence) and SV40 polyadenylation site, by modifying the unique NcoI site at the 5' end of the t-PA gene using NcoI endonuclease and Klenow and adding KpnI linkers to produce a KpnI site.

Referring to Fig. 3, the KpnI-BamHI fragment of pt-PA VPI-LP(K), containing the t-PA gene and SV40 sequences, was isolated and ligated to BamHI-KpnI treated pWAP(H3) to form pWAP-tPA (S); which was then transformed into a TET-sensitive derivative of E. coli strain MC1061. This transformed strain, containing plasmid DNA in which the HindIII-BamHI fragment contains the t-PA gene including the t-PA signal encoding sequence under the transcriptional control of the WAP promoter and followed by the SV40 polyadenylation site, has been deposited in the American Type Culture Collection on March 13, 1986 and given ATCC Accession No. 67032.

Production of milk into which t-PA has been secreted is carried out by excising the HindIII-BamHI fragment from the deposited strain and transferring it by microinjection or other means preferably into the one-cell embryo of a mammal according to conventional methods, as described above. Alternatively, though less desirably, the entire plasmid or other restriction fragments can be introduced into the embryos. Embryos are then nurtured to term *in vivo*. Animals born from such manipulated embryos are screened for the presence of introduced DNA in the genome, and expression of t-PA in the milk is screened for among transgenic, lactating females. The protein from the milk of the adult lactating female animal will be assayed for t-PA by conventional procedures.

Production of Hepatitis B Surface Antigen

Referring to Figure 5, intermediate vectors pWAP-CAT and pHbsSVA were used to construct pWAP-Hbs(S), containing the gene for hepatitis B surface antigen, under the transcriptional control of the WAP promoter and followed by the SV40 polyadenylation site.

The plasmid pWAP-CAT is described above. Plasmid pHbsSVA was constructed as illustrated in Fig. 4. pCLH₃A, containing the SV40 polyadenylation sequence, was restricted with *EcoRI*, *SacI*, and *BglII*. pBSBam, containing the gene for hepatitis B surface antigen, was cut with *EcoRI*, *BamHI* and *PvuI*, and the two mixtures ligated to give pHbsSVA, in which the SV40 sequence was positioned at the 3' end of the Hbs gene, on a *BamHI*-*BglII* fragment. This fragment was then ligated (Fig. 5) to *BamHI* and bacterial alkaline phosphatase-treated pWAP-CAT, transformed into *E. coli* strain MC1061, and the plasmid pWAP-Hbs(S) isolated.

The *BamHI*-*EcoRI* fragment of WAP-Hbs(S) can be excised and used as described above to produce hepatitis B surface antigen. Alternatively, though less desirably, the entire plasmid or other restriction fragments can be introduced into the embryos. Embryos are then nurtured to term *in vivo*. Animals born from such manipulated embryos are screened for the presence of introduced DNA in the genome, and expression of hepatitis B surface antigen in the milk is screened for among transgenic, lactating females. pWAP-Hbs(S) has been deposited in the American Type Culture Collection on March 13, 1986 and given ATCC Accession No. 67033. Applicants' assignee, Integrated Genetics, Inc.,

Both pWAP-Hbs(S) and pWAP-t-PA(S) can be used as cassette vectors in which the hepatitis B surface antigen gene or the t-PA gene can be excised and replaced, using conventional methods, with any desired gene. If desired, the signal encoding sequence from pWAP-t-PA(S) can be left in the vector, and a gene lacking such a sequence inserted downstream of and in frame with it. Alternatively, the signal sequence from pWAP-t-PA(S) or pWAP-Hbs(S) can be removed along with the structural gene and the signal encoding sequence of the substituted gene employed. In addition, the WAP promoter alone can be excised and inserted into another desired expression vector.

Purification and Use

The proteins produced by a process according to the invention are purified from the milk into which they have been secreted and used for their known purposes.

Hepatitis B surface antigen is useful in the production of hepatitis B vaccine.

t-PA is useful in the treatment of thrombolytic disease in which fibrin clot lysis is necessary, as described in European Patent Application 85306957.3. That Patent Application also describes general purification techniques which will be useful for milk-secreted proteins.

Stability in Milk

Table I below shows that, despite the presence in milk of numerous proteases, recombinant t-PA is stable when added to raw goat milk and incubated at 20° or 37°C for 24 hours, with no evidence of loss of activity, as measured using the standard fibrin plate test (results not shown in Table I) or the amidolytic assay described in Wei et al., *id.* Similarly, recombinant hepatitis B surface antigen was found to be stable for at least 24 hours in raw goat milk (data not shown).

Table I

Amidolytic assay for TPA			
	Incubation Time	Temperature	Units/ml
Goat milk alone	—	—	<20, <20
Goat milk & TPA	0	—	437, 368
Goat milk & TPA	24 hours	20°C	419, 434
Goat milk & TPA	24 hours	37°C	467, 507

Other Embodiments

Other embodiments are feasible. For example, other milk serum protein promoters can be used in place of the mouse WAP promoter, and the promoter can be derived from any mammalian species. For example, milk serum protein promoters such as that of β -lactoglobulin can be used, and the rat, rather than mouse, WAP promoter can be used; the rat WAP promoter is described in Campbell et al., *id.* Although less desirable than milk serum protein promoters, casein promoters can be used as well. The protein produced using processes in accordance with this invention can

be any desired protein of therapeutic or industrial importance.

Claims

5

1. A DNA sequence containing a gene encoding a protein, said gene being under the transcriptional control in said DNA sequence of a mammalian casein or milk serum protein promoter which does not naturally control the transcription of said gene, said DNA sequence further comprising DNA enabling secretion of said protein.

10

2. The DNA sequence of Claim 1, wherein said secretion-enabling DNA comprises a secretion signal-encoding sequence interposed between said gene and said promoter.

3. The DNA sequence of Claim 1 wherein said milk serum protein is a whey acid protein.

15

4. The DNA sequence of Claim 2 wherein said signal encoding sequence is the signal encoding sequence naturally associated with said gene encoding said protein.

5. The DNA sequence of Claim 2 wherein said signal encoding sequence is the signal encoding sequence naturally associated with said mammalian casein or milk serum protein promoter.

20

6. The DNA sequence of Claim 1 wherein said DNA sequence includes a transcriptional stop sequence.

7. The DNA sequence of Claim 6 wherein said stop sequence is derived from SV40 virus DNA.

25

8. The DNA sequence of Claim 6 wherein said stop sequence is contained in the polyadenylation sequence of SV40.

9. The DNA sequence of Claim 1 wherein said protein is human tissue plasminogen activator or hepatitis B surface antigen.

30

10. A method for producing a protein comprising the steps of:

(a) inserting into a non-human mammalian embryo a DNA sequence comprising a gene encoding said protein, said gene being under the transcriptional control of a casein or milk serum protein promoter which does not naturally control the transcription of said gene, said DNA sequence comprising DNA enabling secretion of said protein,

35

(b) allowing said embryo to develop into an adult mammal,

(c) inducing lactation in said mammal, or in a female descendant of said mammal in which said gene, promoter, and signal sequence are present in the mammary tissue genome,

(d) collecting milk of said lactating mammal, and

40

(e) isolating said protein from said collected milk.

Patentansprüche

45

1. DNA-Sequenz, enthaltend ein Gen, das ein Protein codiert, wobei das Gen in der DNA-Sequenz unter der Transkriptionskontrolle eines Säugercasein- oder Milchserumproteinpromotors, der natürlicherweise nicht die Transkription des Gens kontrolliert, steht, wobei die DNA-Sequenz weiterhin eine DNA umfaßt, die die Sekretion des Proteins ermöglicht.

50

2. DNA-Sequenz nach Anspruch 1, wobei die die Sekretion ermöglichende DNA eine ein Sekretionssignal codierende Sequenz, die zwischen dem Gen und dem Promotor angeordnet ist, umfaßt.

3. DNA-Sequenz nach Anspruch 1, wobei das Milchserumprotein ein saures Molkeprotein ist.

55

4. DNA-Sequenz nach Anspruch 2, wobei die das Signal codierende Sequenz die natürlicherweise mit der das Protein codierenden Sequenz assoziierte, Signal-codierende Sequenz ist.

5. DNA-Sequenz nach Anspruch 2, wobei die das Signal codierende Sequenz die natürlicherweise mit dem Säuger-

casein- oder Milchserumproteinpromotor assoziierte, Signal-codierende Sequenz ist.

6. DNA-Sequenz nach Anspruch 2, wobei die DNA-Sequenz eine Transkriptionsstoppssequenz umfaßt.
- 5 7. DNA-Sequenz nach Anspruch 6, wobei die Stopp-Sequenz von SV40-Virus-DNA abgeleitet ist.
8. DNA-Sequenz nach Anspruch 6, wobei die Stopp-Sequenz in der Polyadenylierungssequenz von SV40 enthalten ist.
- 10 9. DNA-Sequenz nach Anspruch 1, wobei das Protein menschlicher Gewebsplasminogenaktivator oder das Hepatitis B-Oberflächenantigen ist.
10. Verfahren zur Erzeugung eines Proteins, umfassend die Stufen:
 - 15 a) Insertieren einer DNA-Sequenz, umfassend ein Gen, das das Protein codiert, wobei das Gen unter der Transkriptionskontrolle eines Säugercasein- oder Milchserumproteinpromotors, der natürlicherweise nicht die Transkription des Gens kontrolliert, steht, wobei die DNA-Sequenz DNA umfaßt, die die Sekretion des Proteins ermöglicht, in einen nicht-menschlichen Embryo,
 - b) Entwickelnlassen des Embryos zu einem erwachsenen Säuger,
 - 20 c) Induktion von Laktation bei dem Säuger oder einem weiblichen Nachkommen des Säugers, in dem das Gen, der Promotor und die Signalsequenz in dem Säugergewebsgenom vorhanden sind,
 - d) Gewinnen der Milch des laktierenden Säugers, und
 - e) Isolieren des Proteins aus der gewonnenen Milch.

Revendications

1. Séquence d'ADN contenant un gène codant une protéine, ledit gène étant sous le contrôle de transcription dans ladite séquence d'ADN d'un promoteur de protéine de la caséine ou du lactosérum de mammifère qui ne contrôle pas naturellement la transcription dudit gène, ladite séquence d'ADN comprenant en outre un ADN permettant la sécrétion de ladite protéine.
2. Séquence d'ADN selon la revendication 1, dans laquelle ledit ADN permettant la sécrétion comprend une séquence codant un signal de sécrétion interposée entre ledit gène et ledit promoteur.
3. Séquence d'ADN selon la revendication 1, dans laquelle ladite protéine du lactosérum est une protéine acide du petit-lait.
4. Séquence d'ADN selon la revendication 2, dans laquelle ladite séquence codant un signal est la séquence codant un signal qui est associée naturellement audit gène codant ladite protéine.
5. Séquence d'ADN selon la revendication 2, dans laquelle ladite séquence codant un signal est la séquence codant un signal qui est associée naturellement audit promoteur de protéine de la caséine ou du lactosérum de mammifère.
6. Séquence d'ADN selon la revendication 1, dans laquelle ladite séquence d'ADN comprend une séquence d'arrêt de la transcription.
7. Séquence d'ADN selon la revendication 6, dans laquelle ladite séquence d'arrêt est dérivée de l'ADN du virus SV40.
8. Séquence d'ADN selon la revendication 6, dans laquelle ladite séquence d'arrêt est contenue dans la séquence de polyadénylation de SV40.
9. Séquence d'ADN selon la revendication 1, dans laquelle ladite protéine est l'activateur du plasminogène tissulaire humain ou l'antigène de surface de l'hépatite B.
10. Procédé pour produire une protéine, comprenant les étapes consistant à:
 - (a) insérer dans un embryon de mammifère non humain une séquence d'ADN comprenant un gène codant

ladite protéine, ledit gène étant sous le contrôle de transcription d'un promoteur de protéine de caséine ou de lactosérum qui ne contrôle pas naturellement la transcription dudit gène, ladite séquence d'ADN comprenant un ADN permettant la sécrétion de ladite protéine,

(b) amener ledit embryon à se développer en un mammifère adulte,

(c) induire la lactation dans ledit mammifère ou dans un descendant femelle dudit mammifère dans lequel ledit gène, le promoteur et la séquence signal sont présents dans le génome du tissu mammaire,

(d) recueillir le lait dudit mammifère en lactation, et

(e) isoler ladite protéine à partir dudit lait recueilli.
